Abstract. We establish a new upper bound for the Kullback-Leibler divergence of two discrete probability distributions which are close in a sense that typically the ratio of probabilities is nearly one and the number of outliers is small.

AMS subject classifications: 94A17, 62B10

Key words: Kullback-Leibler divergence, relative entropy, mutual information, information inequality

1. Introduction

Let $\mathbb{P} = (p_i)$ and $\mathbb{Q} = (q_i)$ be two probability distributions on the set $\mathcal{R} = \{1, 2, \dots, r\}$ and

$$D(\mathbb{P} \parallel \mathbb{Q}) = \sum_{i=1}^r p_i \ln \frac{p_i}{q_i} \quad (1)$$

the Kullback-Leibler divergence between these distributions (cf. [1, 3]). The problem of obtaining good upper and lower bounds for the relative entropy attracts considerable interest in information theory (see [1 – 4]). We present here two famous upper bounds (see proofs in [2]):

$$D(\mathbb{P} \parallel \mathbb{Q}) \leq \min \left[\sum_{i=1}^r \frac{p_i^2}{q_i} - 1, \sum_{i=1}^r \sqrt{\frac{p_i}{q_i}} |p_i - q_i| \right]. \quad (2)$$

In the case $|\frac{p_i}{q_i} - 1| \leq \epsilon$ for all i the first bound gives an estimate of order $O(\epsilon)$. In the second bound the distributions should be close in the \mathbf{L}_1 sense. We present here a new upper bound for $D(\mathbb{P} \parallel \mathbb{Q})$ of the first type. However, we achieve the order of approximation $O(\epsilon^2)$ and also allow a possibility of outliers for \mathbb{P} and \mathbb{Q} with a small total mass. We say that $(\mathbb{P}, \mathbb{Q}) \in \mathcal{C}(\epsilon, \delta, c, d)$ if there exists a partition $\mathcal{R} = \mathcal{R}_1 \cup \mathcal{R}_2$ where \mathcal{R}_1 is called a regular set and \mathcal{R}_2 is the set of outliers with the following properties. Assume that for some $\epsilon, \delta > 0$ and some constant $0 < c < 1 < d < \infty$

$$\left| \frac{q_i}{p_i} - 1 \right| \leq \epsilon \quad \forall i \in \mathcal{R}_1, \sum_{j \in \mathcal{R}_2} q_j = \delta, c \leq \frac{q_j}{p_j} \leq d \quad \forall j \in \mathcal{R}_2. \quad (3)$$

The main result is the upper bound of the Kullback-Leibler divergence for small enough $\epsilon, \delta > 0$:

Theorem 1. *For any $(\mathbb{P}, \mathbb{Q}) \in \mathcal{C}(\epsilon, \delta, c, d)$*

$$0 \leq D(\mathbb{P} \parallel \mathbb{Q}) \leq \phi(\epsilon) + \psi(\epsilon, \delta), \quad (4)$$

where $\phi(\epsilon) = \frac{1}{2}\epsilon^2 + 0(\epsilon^3)$, $\psi(\epsilon, \delta) \leq C\delta$ for ϵ, δ small enough, and $C = 2d - c - 1 + \ln \frac{1}{c}$.

Explicit formulas for the functions ϕ and ψ are presented in (12 a, b).

Corollary 1. *Suppose that the joint distribution $P_{X,Y}$ on $\mathcal{R}^{\times 2}$ of random variables X and Y satisfies for all i, j the inequality*

$$|p_{X,Y}(i, j)/p_X(i)p_Y(j) - 1| \leq \epsilon.$$

Then the mutual information between X and Y

$$I(X : Y) = D(p_{X,Y} \parallel p_X \times p_Y) \leq \phi(\epsilon).$$

2. Bound on the ratio of arithmetic and geometric means

Let $0 < c < a < b < d < \infty$, $x_i \in [a, b], i = 1, \dots, r_1$, $y_j \in [c, a) \cup (b, d], j = 1, \dots, r_2$ and $\sum_{j=1}^{r_2} y_j = \delta, r = r_1 + r_2$. Following the strategy used in [5], write $x_i = \lambda_i a + (1 - \lambda_i)b$ and $y_j = \mu_j c + (1 - \mu_j)d$ with $0 \leq \lambda_i, \mu_j \leq 1$. Then for any distribution \mathbb{P} on \mathcal{R} and any convex function f on $[c, d]$

$$0 \leq \sum_{i=1}^{r_1+r_2} p_i f(t_i) - f\left(\sum_{i=1}^{r_1+r_2} p_i t_i\right) = S - T \quad (5)$$

with $t_i \in \{x_i\} \cup \{y_j\}$. Let us estimate the first sum as follows

$$\begin{aligned} S &\leq \sum_{i=1}^{r_1} p_i (\lambda_i f(a) + (1 - \lambda_i)f(b)) + \sum_{i=1}^{r_2} p_i (\mu_i f(c) + (1 - \mu_i)f(d)) \\ &= (f(a) - f(b))p_\lambda + f(b)(1 - \delta) + (f(c) - f(d))p_\mu + f(d)\delta \end{aligned}$$

with $p_\lambda = \sum_{i=1}^{r_1} p_i \lambda_i, p_\mu = \sum_{j=1}^{r_2} p_j \mu_j \leq \delta$.

If we select the convex function as $f(x) = -\ln x$ inequality (5) may be considered as a logarithmic form of the inequality for the ratio of arithmetic and geometric means. We proceed by specifying the second term

$$-T = \ln((a - b)p_\lambda + b(1 - \delta) + (c - d)p_\mu + d\delta)$$

and using the Taylor expansion

$$-T = \ln((a-b)p_\lambda + b(1-\delta) + d\delta) + \frac{1}{\xi}(c-d)p_\mu$$

with $(a-b)p_\lambda + b(1-\delta) + d\delta + (c-d)p_\mu < \xi < (a-b)p_\lambda + b(1-\delta) + d\delta$. So, the RHS of (5) for the function $f(x) = -\ln x$ is estimated as follows:

$$S - T \leq (\ln \frac{b}{a})p_\lambda + (\ln \frac{d}{c})p_\mu + C_1 + \ln[(a-b)p_\lambda + b(1-\delta) + d\delta] - \frac{d-c}{\xi}p_\mu \quad (6)$$

with $C_1 = -(1-\delta)\ln b - \delta\ln d$. An upper bound will be obtained if we estimate ξ from above $\xi < b(1-\delta) + d\delta$ as $c < d$. This result provides an upper bound which is a linear function of p_μ :

$$S - T \leq (\ln \frac{b}{a})p_\lambda + K(d, c, b, \delta)p_\mu + C_1 + \ln[(a-b)p_\lambda + b(1-\delta) + d\delta]. \quad (7)$$

In case the coefficient

$$K = K(d, c, b, \delta) = \ln \frac{d}{c} - \frac{d-c}{b(1-\delta) + d\delta} > 0,$$

an upper bound is obtained by selecting $p_\mu = \delta$. In the case $K < 0$ we select $p_\mu = 0$. In any case, the term proportional to p_μ does not depend on p_λ and the value p_λ^* maximizing the RHS in (7) is the solution of equation

$$\ln b - \ln a + \frac{a-b}{(a-b)p_\lambda + b(1-\delta) + d\delta} = 0, \text{ i.e. } p_\lambda^* = \frac{b(1-\delta) + d\delta}{b-a} - \frac{1}{\ln b - \ln a}. \quad (8)$$

It is straightforward to check that the second derivative is negative at p_λ^* . Next, note that

$$p_\lambda^* > \frac{b}{b-a} - \frac{1}{\ln b - \ln a} > 0$$

and $p_\lambda^* < 1 - \delta$ for $\delta < \delta^* = \frac{1}{d-a}(\frac{b-a}{\ln b - \ln a} - a)$.

Let $L(a, b) = \frac{b-a}{\ln b - \ln a}$. Combining all results together we obtain that

$$S - T \leq \ln \Lambda(a, b) + \delta \Gamma(a, b, c, d, \delta), \quad (9)$$

where

$$\ln \Lambda(a, b) = \frac{b}{L(a, b)} - 1 - \ln b + \ln(L(a, b)). \quad (10)$$

The function $\Lambda(a, b)$ in first term may be represented as follows (cf. [5]):

$$\Lambda(a, b) = abL(a, b)/G^2(a, b), G(a, b) = \frac{1}{e}(b^b/a^a)^{1/(b-a)}.$$

in the case $K(d, c, b, \delta) > 0$ we have

$$\Gamma(a, b, c, d, \delta) = \frac{(d-a)\ln b - (d-b)\ln a}{b-a} - \ln c + \frac{d-c}{b + (d-b)\delta} \quad (11a)$$

and in the case $K(d, c, b, \delta) \leq 0$

$$\Gamma(a, b, c, d, \delta) = \frac{(d-a)\ln b - (d-b)\ln a}{b-a} - \ln c. \quad (11b)$$

Observe that $\Gamma(a, b, c, d, \delta) > 0$ in both cases.

3. Proof of the Theorem 1

Let us apply the results of the previous section with $t_i = \frac{q_i}{p_i}$, $a = 1 - \epsilon$, $b = 1 + \epsilon$. By straightforward calculations the expression in (10) admits the expansion

$$\ln \Lambda(1 - \epsilon, 1 + \epsilon) = \epsilon + \frac{1}{3}\epsilon^2 - \epsilon + \frac{1}{2}\epsilon^2 - \frac{1}{3}\epsilon^2 + \dots = \frac{1}{2}\epsilon^2 + \dots$$

For ϵ small enough both expressions in (11a,b) are bounded by $2d - c - 1 + \ln \frac{1}{c}$ by inspection. Now the Theorem follows from (9) with

$$\phi(\epsilon) = (1 + \epsilon)F(\epsilon)^{-1} - 1 - \ln(1 + \epsilon) - \ln F(\epsilon), \quad F(\epsilon) = \left(\ln \frac{1 + \epsilon}{1 - \epsilon} \right) / 2\epsilon \quad (12a)$$

and

$$\psi(\epsilon, \delta) = \delta \left[(d - 1 + \epsilon)F(\epsilon) - \ln c + \frac{d - c}{1 + (d - 1 - \epsilon)\delta} \right]. \quad (12b)$$
